Available online 23 November 1999.

Abstract

The Distributed Link Service^[5] provides hypermedia services, layered on top of, but independent of, the underlying document data services provided by the World Wide Web. This model enables enormous flexibility for providing and manipulating links and designing information architectures, but conversely abandons any guarantee of synchronicity between changes in the data layer and the links layer.

This paper contrasts this approach to link management with the more generally accepted (and safer) solution of a closed information environment (perhaps in the form of an object-oriented SGML database), and presents an expanded open hypermedia service for the WWW composed of link

Abstract:

Digital libraries should include all the enhanced search functionality that can be provided by using state-of-the-art electronic tools. With respect to this main goal, the support of intuitive searches by means of employing hypertextual features is important. In order to include these features into the browsing functionality also for raster image representations of documents, the underlying implicit and explicit hypertext structure of library objects has to be modelled and detected. This internal conversion of real library objects into hypertext objects has to be done automatically as far as possible in order to make it feasible at all. Yet, this conversion has to be flexible enough to cope with the whole range of library objects. In order to do so it has to use explicit information, such as words, phrases, paragraphs etc., as well as all the implicit information contained in fonts and layout. In this chapter we will therefore describe the automatic hypertext conversion of printed arti...

Abstract

Source code browsing is an important part of program comprehension. Browsers expose syntactic relationships (such as between object references and definitions) in GUI-accessible relationships are derived using tools which perform static analysis on the original software. Implementing such browsers is tricky. Program comprehension strategies vary, and it is not the right browsing support. Analysis tools to derive the relevant cross-reference relationships to build. Tools to browse distributed documents require extensive coding for the GUI, as well as communications. Therefore, there are powerful motivations for using existing static analysis with WWW technology to implement browsers for distributed software projects. The CHIME provides a flexible, customizable platform for inserting HTML links into software documents generated by existing software analysis tools. Using the CHIME specification language, a retargetable database interface, it is possible to quickly incorporate a range of different legacy software documents, into an existing, legacy software development environment. This environment offer customized browsing support with a well-known GUI. This paper describes the CHIME describes our experience with several re-targeting efforts of this system.
